

# DATA MINING 2

## Exercises – Evaluation, NN, Ensemble

---

Riccardo Guidotti

a.a. 2019/2020

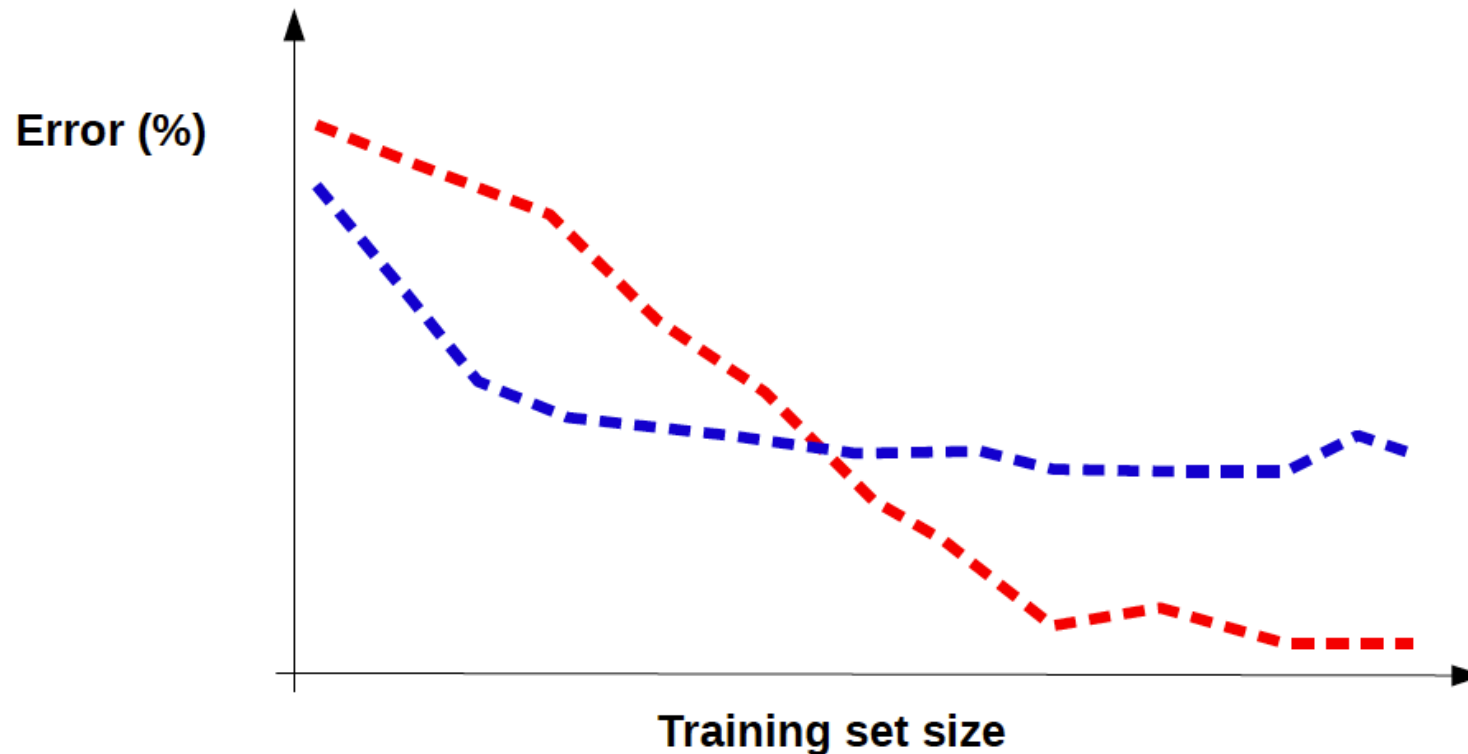

UNIVERSITÀ DI PISA

# Evaluation

---

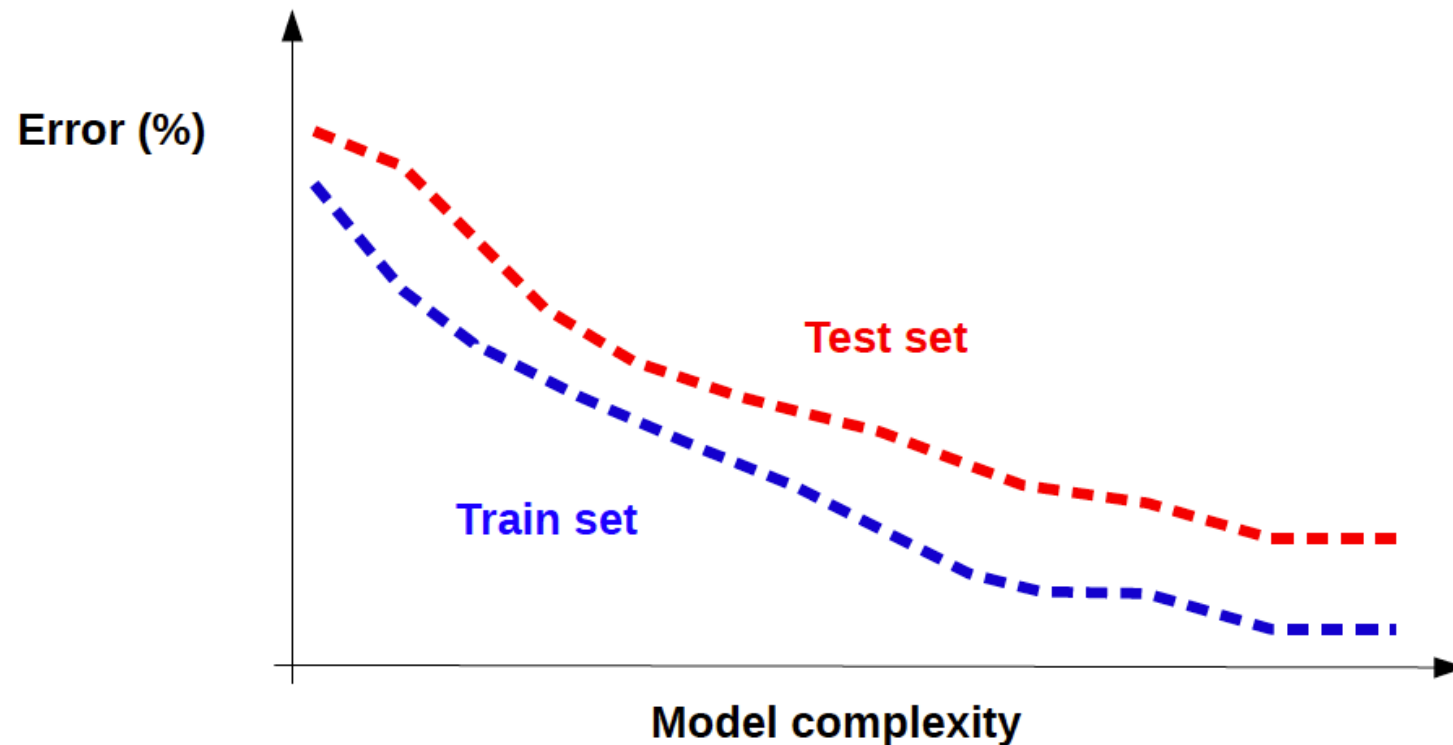

# Learning Curves

- Two classification methods produce the following learning curves. What can we conclude about them?

# Fitting Graphs

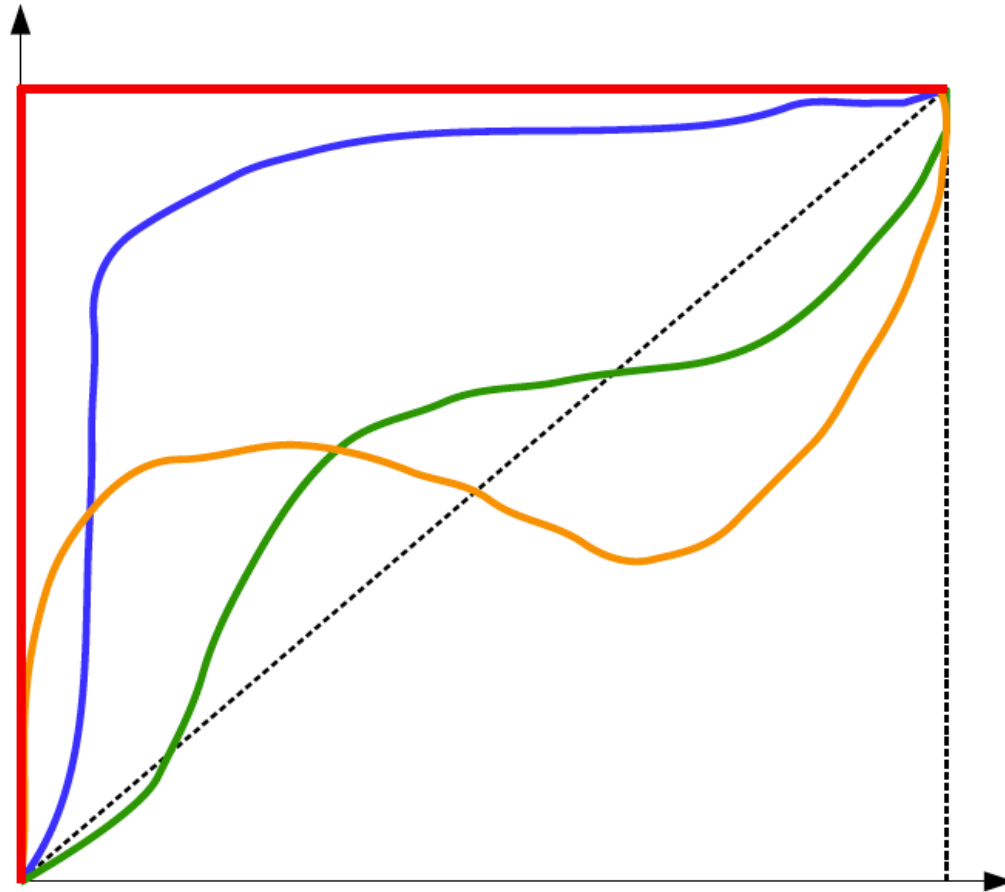

- Our classification method produces the following fitting graph. What can we conclude about the model and/or the dataset?

# Evaluation Curves

---

- Which of the following curves could be a ROC?
- Which could be a Lift chart?

# Evaluation Curves - Solution

- Which of the following curves could be a ROC?
  - Answer: all, excepted the orange one: TPR and FPR (on the axes) never decrease
- Which could be a Lift chart?
  - Answer: as for ROC, but now also the red one is impossible: you need to classify as positive several records (X axis) to reach 100% of TPR (Y axis)

# Neural Networks

# Predict with a Neural Network

Given the neural network below (on the left), apply it to the test set provided (on the right). The weights are reported beside each connection, while the activation function is simply  $f(S) = \text{sign}(S)$ , i.e. -1 for positive values, +1 for positive ones and 0 for  $S=0$ . For each case, show the output also of the nodes on the hidden layer.

# Ensemble

---

# Ensemble

---

- We have 3 independent models for the same data, with poor performances
  - Error1 = 45%
  - Error2 = 40%
  - Error3 = 35%
- Is it better to use Model3 alone or to make bagging with all the three models?

# Ensemble - Solution

---

- TODO: compute the probability of error of the ensemble
- Standard formula (case for 25 models):

$$\sum_{i=13}^{25} \binom{25}{i} \epsilon^i (1 - \epsilon)^{25-i}$$

- Implicitly enumerates all cases with more errors than correct answers ( $i \geq 13$  errors against  $25-i \leq 12$  correct ones)
  - However, it works only when all models have the same error  $\epsilon$
- Here we have to explicitly enumerate all cases

# Ensemble - Solution

---

- Probability of success  and failure  of each:

– Model1 =	 .45	 .55
– Model2 =	 .40	 .60
– Model3 =	 .35	 .65

# Ensemble - Solution

---

- We have 8 possible cases

Model1

Model2

Model3

# Ensemble - Solution

---

- We have 8 possible cases

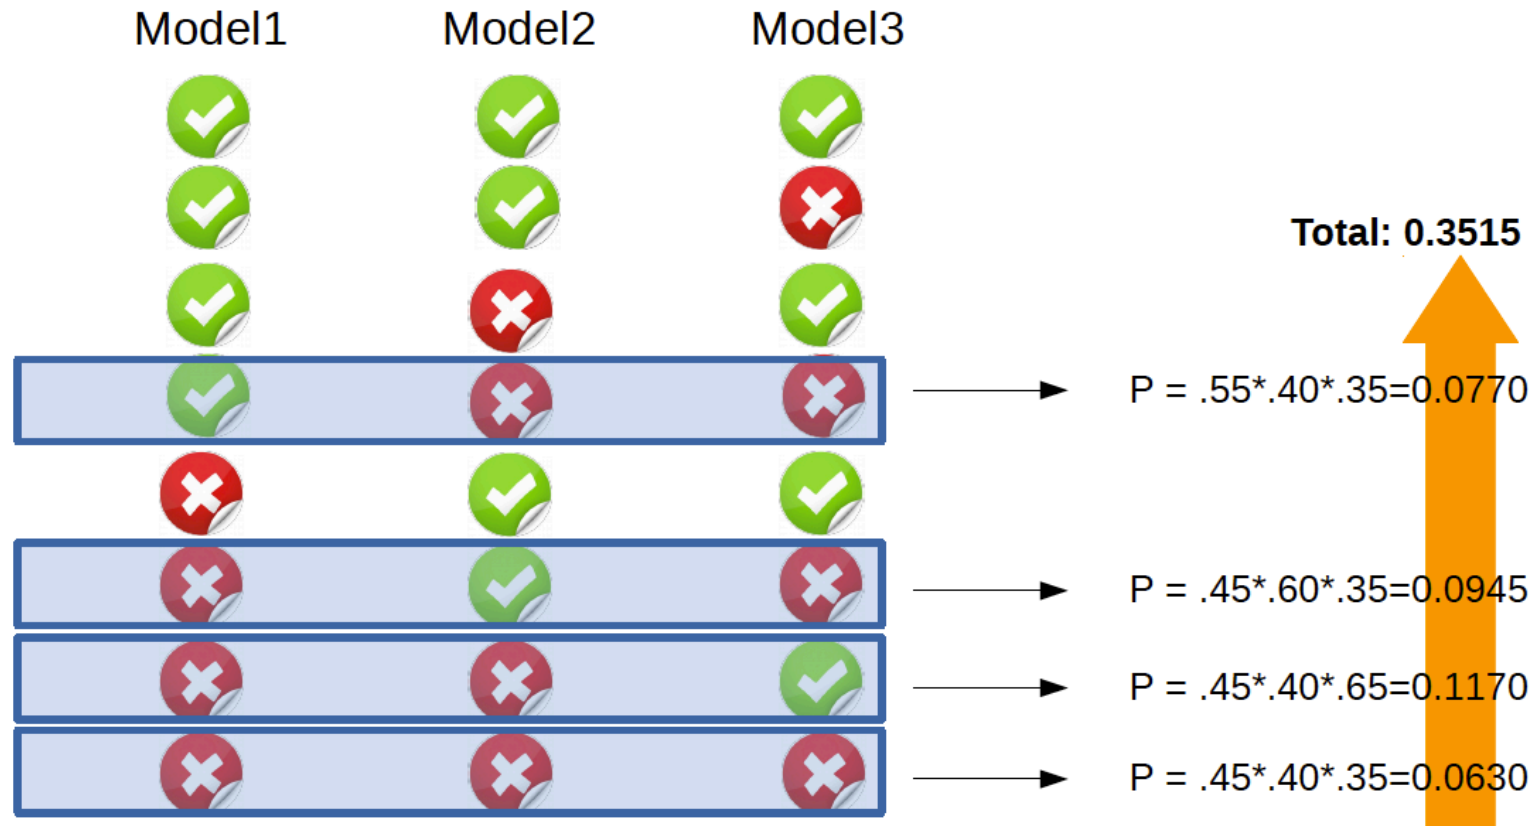

Model1	Model2	Model3

# Ensemble - Solution

- We have 8 possible cases

- Probability of success  and failure  of each:

- Model1 =  .45       .55
- Model2 =  .40       .60
- Model3 =  .35       .65

# Ensemble - Solution

---

- Outcome:
  - The “expert” model (Model3) has 35% of error
  - The bagging model has 35.15% of error
  - In this specific case Bagging is not better than the “expert” alone...

# AdaBoost
