Master Program in *Data Science and Business Informatics* **Statistics for Data Science** Lesson 09 - Expectation and variance. Computations with random variables

Salvatore Ruggieri

Department of Computer Science University of Pisa, Italy salvatore.ruggieri@unipi.it

Expectation of a discrete random variable

• Buy lottery ticket every week, p = 1/10000, what is probability of winning at k^{th} week?

$$X \sim Geo(p)$$
 $P(X = k) = (1 - p)^{k-1} \cdot p$ for $k = 1, 2, ...$

• What is the average number of weeks to wait (expected) before winning?

$$E[X] = \sum_{k=1}^{\infty} k \cdot (1-p)^{k-1} \cdot p = \frac{1}{p}$$

because
$$\sum_{k=1}^{\infty} k \cdot x^{k-1} = \frac{1}{(1-x)^2}$$

DEFINITION. The *expectation* of a discrete random variable X taking the values a_1, a_2, \ldots and with probability mass function p is the number

$$\mathbf{E}[X] = \sum_{i} a_i \mathbf{P}(X = a_i) = \sum_{i} a_i p(a_i).$$

• Expected value, mean value (weighted by probability of occurrence), center of gravity See seeing-theory.brown.edu

Expected value may be infinite or may not exist!

- Fair coin: win 2^k euros if first H appears at k^{th} toss
 - X with p.m.f. $p(2^k) = 2^{-k}$ for k = 1, 2, ...
 - p() is a p.m.f. since $\sum_{k=1}^{\infty} 2^{-k} = 1$
 - $E[X] = \sum_{k=1}^{\infty} 2^k \cdot 2^{-k} = \sum_{k=1}^{\infty} 1 = \infty$
- Expectation does not exist when $\sum_i a_i p(a_i)$ does not converge
 - X with p.m.f. $p(2^k) = p(-2^k) = 2^{-k}$ for k = 2, 3, ...
 - $E[X] = \sum_{k=2}^{\infty} (2^k \cdot 2^{-k} 2^k \cdot 2^{-k}) = \sum_{k=2}^{\infty} (1-1) = 0$ wrong!
 - $E[X] = \sum_{k=2}^{\infty} 2^k \cdot 2^{-k} \sum_{k=2}^{\infty} 2^k \cdot 2^{-k} = \infty \infty$ undefined
 - E[X] is finite if $\sum_i |a_i| p(a_i) < \infty$
 - ▶ In the case above, $\sum_{k=2}^{\infty} (|2^k| \cdot 2^{-k} + |-2^k| \cdot 2^{-k}) = \infty$

[St. Petersburg paradox]

using $\sum_{k=0}^{\infty}a^k=rac{1}{1-a}$ for |a|<1

Expectation of some discrete distributions

- Expectation of some discrete distributions
 - ► $X \sim U(m, M)$ E[X] = (m+M)/2 $\Box \sum_{i=m}^{M} \frac{i}{M-m+1} = \frac{1}{M-m+1} \sum_{i=0}^{M-m} (m+i) = m + (M-m)/2 = \frac{m+M}{2}$
 - $X \sim Ber(p)$ E[X] = p
 - $\ \ \square \ \ 0\cdot(1-p)+1\cdot p=p$

[Mean may not belong to the support]

- $X \sim Bin(n,p)$ $E[X] = n \cdot p$
 - □ Because . . . we'll see later

•
$$X \sim NBin(n, p)$$
 $E[X] = \frac{n \cdot p}{1-p}$

- □ Because ... we'll see later
- $X \sim Poi(\mu)$ $E[X] = \mu$

 \Box Because, when $n \to \infty$: $Bin(n, \mu/n) \to Poi(\mu)$

Expectation of a continuous random variable

DEFINITION. The *expectation* of a continuous random variable X with probability density function f is the number

$$\mathbf{E}[X] = \int_{-\infty}^{\infty} x f(x) \, \mathrm{d}x.$$

Expectation of some continuous distributions

$$X \sim U(\alpha, \beta) \quad E[X] = (\alpha + \beta)/2$$

$$X \sim Exp(\lambda) \quad E[X] = \frac{1}{\lambda}$$

$$\square \text{ Because } \int_0^\infty x\lambda e^{-\lambda x} dx = \left[-e^{-\lambda x}(x+\frac{1}{\lambda})\right]_0^\infty = e^0(0+\frac{1}{\lambda})$$

$$S \sim N(\mu, \sigma^2) \quad E[X] = \mu$$

$$\square \text{ Because: } \int_{-\infty}^\infty x \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{2}(\frac{x-\mu}{\sigma})^2} dx = \mu + \int_{-\infty}^\infty (x-\mu) \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{1}{2}(\frac{x-\mu}{\sigma})^2} dx = \sum_{z=\frac{x-\mu}{\sigma}}$$

$$= \mu + \sigma \int_{-\infty}^\infty z \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2} dz = \mu$$

• $X \sim Erl(n, \lambda)$ $E[X] = n/\lambda$ \Box Because ... we'll see later

Expected value may not exists!

• Cauchy distribution

$$f(x)=\frac{1}{\pi(1+x^2)}$$

• $X_1, X_2 \sim N(0, 1)$ i.i.d., $X = X_1/X_2 \sim Cau(0, 1)$

$$E[X] = \int_{-\infty}^{0} xf(x)dx + \int_{0}^{\infty} xf(x)dx$$

•
$$\int_{-\infty}^{0} xf(x)dx = \left[\frac{1}{2\pi}\log(1+x^2)\right]_{-\infty}^{0} = -\infty$$

•
$$\int_{0}^{\infty} xf(x)dx = \left[\frac{1}{2\pi}\log(1+x^2)\right]_{0}^{\infty} = \infty$$

$$E[X] = -\infty + \infty$$

• E[X] is finite if $\int_{-\infty}^{\infty} |x| f(x) dx < \infty$

Mean value does not always make sense in your data analytics project!

$E[g(X)] \neq g(E[X])$

- Recall that *velocity = space/time*, and then *time = space/velocity*!
- Vector v of speed (Km/h) to reach school and their probabilities p using feet, bike, bus, train:

v = c(5, 10, 20, 30) p = c(0.1, 0.4, 0.25, 0.25)

- Distance house-schools is 2 Km
- What is the average time to reach school?
 - 2/sum(v*p) i.e., space/E[velocity]
 - sum(2/v*p) i.e., E[space/velocity]
- X = velocity, g(X) = 2/X time to reach school
 - $E[g(X)] \neq g(E[X])$

The change of variable formula (or rule of the lazy statistician)

- $X \sim U(0, 10)$, width of a square field, E[X] = 5
- $g(X) = X^2$ is the area of the field, E[g(X)] = ?
- $F_g(a) = P(g(X) \le a) = P(X \le \sqrt{a}) = \sqrt{a}/10$ for $0 \le a \le 100$
- Hence, $f_g(a) = dF_g(a)/da = 1/20\sqrt{a}$
- $E[g(X)] = \frac{1}{20} \int_0^{100} \frac{x}{\sqrt{x}} dx = \frac{1}{20} \frac{2}{3} \left[x^{3/2} \right]_0^{100} = \frac{100}{3}$
- Alternatively, $E[g(X)] = \int_0^{10} x^2 \frac{1}{10} dx = \frac{1}{10} \frac{1}{3} \left[x^3\right]_0^{10} = 100/3$

 $[E[g(X)] \neq g(E[X])]$

[later on, a general theorem]

THE CHANGE-OF-VARIABLE FORMULA) Let X be a random variable, and let $g : \mathbb{R} \to \mathbb{R}$ be a function. If X is discrete, taking the values a_1, a_2, \ldots , then

$$\mathbf{E}[g(X)] = \sum_{i} g(a_i) \mathbf{P}(X = a_i) \,.$$

If X is continuous, with probability density function f, then

$$\mathbf{E}\left[g(X)\right] = \int_{-\infty}^{\infty} g(x)f(x)\,\mathrm{d}x.$$

See R script

Theorem (Change of units) E[rX + s] = rE[X] + s

- Example: for Y = 1.8X + 32, we have E[Y] = 1.8E[X] + 32 [0
 - [Celsius to Fahrenheit]

• Corollary.

$$E[X - E[X]] = E[X] - E[X] = 0$$

• **Theorem.** Expectation minimizes the square error, i.e., for $a \in \mathbb{R}$:

$$E[(X - E[X])^2] \le E[(X - a)^2]$$

• Proof. (sketch) set
$$\frac{d}{da} \int_{-\infty}^{\infty} (x-a)^2 f(x) dx = 0$$

Entropy of a random variable

- The **Shannon's information entropy** is the average level of "information", "surprise", or "uncertainty" inherent to the variable's possible outcomes
 - Information is inversely proportional to probability
 - □ Highly likely events carry very little new information
 - Highly unlikely events carry more information
 - Information content ic() of two independent events should sum up

$$\Box ic(p(A \cup B)) = ic(p(A)) + ic(p(B)) = ic(p(A)p(B))$$

- $\Box ic(p(\Omega)) = ic(1) = 0$
- \Box ic(p(A)) ≥ 0

•
$$H(X) = E[-\log p(X)]$$
 (discrete) $H(X) = E[-\log f(X)]$ (continuous)

$$H(X) = -\sum_{i} p(a_i) \log p(a_i) \qquad \qquad H(X) = -\int_{-\infty}^{\infty} f(x) \log f(x) dx$$

▶ For X discrete,
$$H(X) \ge 0$$
 since $-\log p(X) = \log \frac{1}{p(X)} \ge 0$
□ reached when $p(a_1) = 1$ and $p(a_i) = 0$ for $i \ne 1$

For
$$X \sim Ber(p)$$
, $H(X) = -p \log p - (1-p) \log (1$

 $\frac{1}{p(a_i)}$

 $\log \frac{1}{p(a_i)}$

Computation with discrete random variables

Theorem

For a discrete random variable X, the p.m.f. of Y = g(X) is:

$$P_Y(Y = y) = \sum_{g(x)=y} P_X(X = x) = \sum_{x \in g^{-1}(y)} P_X(X = x)$$

- **Proof.** $\{Y = y\} = \{g(X) = y\} = \{x \in g^{-1}(y)\}$
- **Corollary** (the change-of-variable formula):

$$E[g(X)] = \sum_{y} y P_{Y}(Y = y) = \sum_{y} y \sum_{g(x)=y} P_{X}(X = x) = \sum_{x} g(x) P_{X}(X = x)$$

Example

- $X \sim U(1, 200)$ number of tickets sold
- Capacity is 150
- $Y = max\{X 150, 0\}$ overbooked tickets

$$P_Y(Y = y) = \begin{cases} 150/200 & \text{if } y = 0 \\ 1/200 & \text{if } 1 \le y \le 50 \\ g^{-1}(y) = \{y + 150\} \end{cases}$$

• Hence:

$$E[Y] = 0 \cdot \frac{150}{200} + \frac{1}{200} \cdot \sum_{y=1}^{50} y = 6.375$$

• or using the change-of-variable formula:

$$E[Y] = \frac{1}{200} \cdot \sum_{x=1}^{200} \max\{X - 150, 0\} = \frac{1}{200} \cdot \sum_{x=151}^{200} (X - 150) = 6.375$$

Computation with continuous random variables

Theorem

For a continuous random variable X, the density functions of Y = g(X) when g() is increasing/decreasing are:

$$F_Y(y) = F_X(g^{-1}(y))$$
 $f_Y(y) = f_X(g^{-1}(y)) \left| \frac{dg^{-1}(y)}{dy} \right|$

• **Proof.** (for g() increasing) Since g() is invertible and $g(x) \le y$ iff $x \le g^{-1}(y)$:

$$F_Y(y) = P_Y(g(X) \le y) = P_X(X \le g^{-1}(y)) = F_X(g^{-1}(y))$$

and then:

$$f_Y(y) = \frac{dF_Y(y)}{dy} = \frac{dF_X(g^{-1}(y))}{dy} = \frac{dF_X(g^{-1}(y))}{dg^{-1}} \frac{dg^{-1}(y)}{dy} = f_X(g^{-1}(y)) \frac{dg^{-1}(y)}{dy}$$

Exercise: show the case g() decreasing!

CHANGE-OF-UNITS TRANSFORMATION. Let X be a continuous random variable with distribution function F_X and probability density function f_X . If we change units to Y = rX + s for real numbers r > 0and s, then

$$F_Y(y) = F_X\left(\frac{y-s}{r}\right)$$
 and $f_Y(y) = \frac{1}{r}f_X\left(\frac{y-s}{r}\right)$.

- For $X \sim N(\mu, \sigma^2)$, how is $Z = \frac{X}{\sigma} + \frac{-\mu}{\sigma} = \frac{X-\mu}{\sigma}$ distributed? $f_Z(z) = \sigma f_X(\sigma y + \mu) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}y^2}$
- Hence, $Z \sim N(0, 1)$
- In particular, for $X \sim N(\mu, \sigma^2)$, we have:

$$P(X \le a) = P(Z \le \frac{a-\mu}{\sigma}) = \Phi(\frac{a-\mu}{\sigma})$$

Example: $\Lambda(\mu, \sigma^2)$

Log-normal distribution $Y = e^X$ for $X \sim N(\mu, \sigma^2)$, i.e., $log(Y) \sim N(\mu, \sigma^2)$

- $Y = g(X) = e^X$ Support is $]0, \infty[$
- $g(x) = e^x$ is increasing, and $g^{-1}(y) = \log y$, and $\frac{dg^{-1}(y)}{dy} = \frac{1}{y}$

$$F_Y(y) = F_X(g^{-1}(y)) = \Phi(\frac{\log y - \mu}{\sigma}) \qquad f_Y(y) = f_X(g^{-1}(y))\frac{dg^{-1}(y)}{dy} = \frac{1}{y\sigma\sqrt{2\pi}}e^{-\frac{1}{2}(\frac{\log y - \mu}{\sigma})^2}$$

- $E[g(X)] = \int_{-\infty}^{\infty} g(x) f_X(x) dx = \int_{-\infty}^{\infty} y f_Y(y) dy = e^{\mu + \sigma^2/2}$
- Plausible and empirically adequate model for:
 - ▶ length of comments in posts, dwell time reading online articles, length of chess games, ...
 - ▶ size of living tissue, number of hospitalized cases in epidemics, blood pressure, ...
 - ▶ income of 97%-99% of the population, the number of citations, log of city size, ...
 - times to repair a maintainable system, size of audio-video files, amount of internet traffic per unit time, ...

See R script

Common distributions

- Probability distributions at Wikipedia
- Probability distributions in R
- C. Forbes, M. Evans, N. Hastings, B. Peacock (2010) Statistical Distributions, 4th Edition Wiley

Relationships among common distributions. Solid lines represent transformations and special cases, dashed lines represent limits. Adapted from Leemis (1986). 16 /

Example

- $X \sim U(0,1)$ radius $f_X(x) = 1$ $F_X(x) = x$ for $x \in [0,1]$ • $Y = g(X) = \pi \cdot X^2$ Support is $[0,\pi]$
- $g(x) = \pi x^2$ is increasing, and $g^{-1}(y) = \sqrt{\frac{y}{\pi}}$, and $\frac{dg^{-1}(y)}{dy} = \frac{1}{2\sqrt{\pi y}}$

$$F_Y(y) = F_X(g^{-1}(y)) = \sqrt{\frac{y}{\pi}}$$
 $f_Y(y) = f_X(g^{-1}(y)) \frac{dg^{-1}(y)}{dy} = \frac{1}{2\sqrt{\pi y}}$

Do not lift distributions from a data column to a derived column in your data analytics project! See R script

• Notice that: $g(E[X]) = \pi/4 \le E[g(X)] = \int_0^1 g(x) f_X(x) dx = \int_0^\pi y f_Y(y) dy = \frac{\pi}{3}$

JENSEN'S INEQUALITY. Let g be a convex function, and let X be a random variable. Then

 $g(\mathbf{E}[X]) \le \mathbf{E}[g(X)].$

• f() is convex if $f(tx_1 + (1-t)x_2) \le tf(x_1) + (1-t)f(x_2)$ for $t \in [0,1]$

Corollary and Example

Corollary (see [T, Ex. 8.11]. For a concave function g, namely $g''(x) \le 0$: $g(E[X]) \ge E[g(X)]$

- $\log(x)$ is concave since $\log''(x) = -1/x^2 \le 0$
- Let X be discrete with finite domain of n elements
 - By corollary above:

$$H(X) = E[\log \frac{1}{p(X)}] \le \log E[\frac{1}{p(X)}]$$

By change of variable:

$$E[\frac{1}{p(X)}] = \sum_{i} \frac{p(a_i)}{p(a_i)} = n$$

and then maximum entropy is:

 $H(X) \leq \log n$

• E.g., $X \sim Ber(p)$, maximum entropy (uncertainty) for equiprobable events p = 1/2

Variance

- Investment A. P(X = 450) = 0.5 P(X = 550) = 0.5 E[X] = 500
- Investment B. P(X = 0) = 0.5 P(X = 1000) = 0.5 E[X] = 500
- Spread around the mean is important!

Variance and standard deviations

The variance Var(X) of a random variable X is the number:

$$Var(X) = E[(X - E[X])^2]$$

 $\sigma_X = \sqrt{Var(X)}$ is called the *standard deviation* of X.

- The standard deviation has the same dimension as E[X] (and as X)
- For X discrete, $Var(X) = \sum_{i} (a_i E[X])^2 p(a_i)$
- Investment A. $Var(X) = 50^2$ and $\sigma_X = 50$
- Investment B. $Var(X) = 500^2$ and $\sigma_X = 500$

Examples

• For $a \in \mathbb{R}$:

$$\mathsf{E}[|X-\mathsf{a}|] \leq \sqrt{\mathsf{E}[(X-\mathsf{a})^2]}$$

• Apply Jensen's ineq. for $g(y) = y^2$ convex on the r.v. Y = |X - a|

• Median minimizes absolute deviation, i.e., for $a \in \mathbb{R}$:

$$E[|X - m_X|] \le E[|X - a|]$$

- **Prove it!** (for continuous functions) Hint: $\frac{d}{dx}|x| = x/|x|$
- Maximum distance between expectation and median:

$$|\mathcal{E}[X] - m_X| \leq \mathcal{E}[|X - m_X|] \leq \mathcal{E}[|X - \mathcal{E}[X]|] \leq \sqrt{\mathcal{E}[(X - \mathcal{E}[X])^2]} = \sigma_X$$

• Apply Jensen's ineq. for g(y) = |y| convex on the r.v. $Y = X - m_X$ plus two results above

Mode

- For discrete r.v. X with p.m.f. p(): the values a such that p(a) is maximum, i.e.: $\arg \max_{a} p(a)$
 - Can be more than one, e.g., in Ber(0.5)
- For continuous r.v. X with d.f. f(): the values x such that f(x) is a local maximum, e.g.:

$$f'(x) = 0$$
 and $f''(x) < 0$

- Notice: **local** maximum!
- Unimodal distribution = that have only one mode

Variance

Theorem. $Var(X) = E[X^2] - E[X]^2$ **Proof.**

$$Var(X) = E[(X - E[X])(X - E[X])]$$

= $E[X^2 + E[X]^2 - 2XE[X]]$
= $E[X^2] + E[X]^2 - E[2XE[X]]$
= $E[X^2] + E[X]^2 - 2E[X]E[X] = E[X^2] - E[X]^2$

• $E[X^2]$ is called the *second moment* of X

 $\int_{-\infty}^{\infty} x^2 f(x) dx$

Corollary.

$$Var(rX + s) = r^2 Var(X)$$

Prove it!

• Variance insensitive to shift s!

Variance may be infinite or may not exist!

Standard deviation σ_X is a measure of the margin of error around a predicted value (e.g., temperature "20 \pm 1.5").

An infinite or non-existent margin of error is no prediction at all.

- Variance may not exists!
 - If expectation does not exist!
 - Also in cases when expectation exists
 - \Box We'll see later *Power laws*.
- Variance can be infinite
 - Distributions have fat upper tails that decrease at an extremely slow rate.
 - ► The slow decay of probability increases the odds of very extreme values (*outliers*)
 - E.g., e^X for $X \sim Cau(0,1)$

[log-Cauchy distribution]

Variance

• Variance of some discrete distributions

See seeing-theory.brown.edu

Variance

- Variance of some continuous distributions
 - $X \sim U(\alpha, \beta)$ $E[X] = (\alpha + \beta)/2$ $Var(X) = (\beta \alpha)^2/12$
 - □ **Prove it!** Recall that $f(x) = \frac{1}{(\beta \alpha)}$
 - $X \sim Exp(\lambda)$ $E[X] = 1/\lambda$ $Var(X) = 1/\lambda^2$
 - **Prove it!** Recall that $f(x) = \lambda e^{-\lambda x}$

•
$$X \sim N(\mu, \sigma^2)$$
 $E[X] = \mu$ $Var(X) = \sigma^2$

□ **Prove it!** Hint: use $z = \frac{x-\mu}{\sigma}$ and integration by parts.

•
$$X \sim Erl(n, \lambda)$$
 $E[X] = n/\lambda$ $Var(X) = n/\lambda^2$

□ Because ... we'll see later

E[] and *Var*() of random variables with bounded support

Assume $a \le X \le b$, or more generally $P(a \le X \le b) = 1$ It turns out that expectation and variance are finite! [almost surely or a.s.]

- $a \leq E[X] \leq b$
 - E.g., for X continuous, $E[X] = \int_a^b xf(x)dx \le \int_a^b bf(x)dx = b$
- $0 \leq Var(X) \leq (b-a)^2/4$

Proof.

- ► For $\gamma \in \mathbb{R}$, consider $E[(X \gamma)^2] = \gamma^2 2\gamma E[X] + E[X^2]$
- It is minimum for $\gamma = E[X]$ (consider $\frac{d}{d\gamma}(\gamma^2 2\gamma a + b)$)
- ► Thus, $E[(X E[X])^2] = Var(X) \le E[(X \gamma)^2]$
- For $\gamma = (a+b)/2$, we have $(X \gamma)^2 \le (b \gamma)^2$ and then:

$$Var(X) \leq E[(X - \frac{(a+b)}{2})^2] \leq (b - \frac{(a+b)}{2})^2 = \frac{(b-a)^2}{4}$$

• Exercise at home: show that the bound $(b-a)^2/4$ can be reached.
