#### Statistics for Data Science

Lesson 27 - Bootstrap and resampling methods

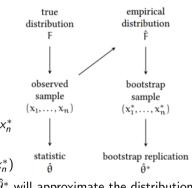

#### Salvatore Ruggieri

Department of Computer Science University of Pisa salvatore.ruggieri@unipi.it

# Bootstrap principle

- Let  $X_1, \ldots, X_n \sim F$  be a random sample
  - ▶ with unknown distribution F
- Estimator  $T = h(X_1, \dots, X_n)$ , e.g.,  $\bar{X}_n = (X_1 + \dots + X_n)/n$
- From a dataset  $x_1, \ldots, x_n$ , we can
  - derive a point estimate  $\hat{\theta} = h(x_1, \dots, x_n)$
  - or, derive an estimate  $\hat{F}$  of F
- From  $\hat{F}$  we can generate (a lot of) bootstrap samples  $x_1^*, \ldots, x_n^*$ 
  - ightharpoonup as realizations of  $X_1^*,\ldots,X_n^*\sim \hat{F}$
  - and then (a lot of) bootstrap point estimates  $\hat{ heta}^* = h(x_1^*, \dots, x_n^*)$
- By the **Glivenko-Cantelli Thm**, the empirical distribution of  $\hat{\theta}^*$  will approximate the distribution of  $T^* = h(X_1^*, \dots, X_n^*)$  and then of T

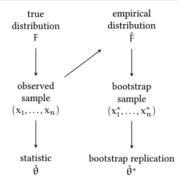

BOOTSTRAP PRINCIPLE. Use the dataset  $x_1, x_2, ..., x_n$  to compute an estimate  $\hat{F}$  for the "true" distribution function F. Replace the random sample  $X_1, X_2, ..., X_n$  from F by a random sample  $X_1^*, X_2^*, ..., X_n^*$  from  $\hat{F}$ , and approximate the probability distribution of  $h(X_1, X_2, ..., X_n)$  by that of  $h(X_1^*, X_2^*, ..., X_n^*)$ .

- How to derive  $\hat{F}$  from  $x_1, \ldots, x_n$ ?
- If we know nothing about F, use the empirical distribution:

$$\hat{F}(a) = F_n(a) = \frac{|\{i \in 1, \dots, n \mid x_i \le a\}|}{n}$$

- How to generate a bootstrap sample  $x_1^*, \ldots, x_n^*$ ?
  - $\triangleright x_i^*$  is chosen randomly from  $\hat{F}$
  - i.e.,  $x_i^*$  s chosen randomly from  $x_1, \ldots, x_n$  (our dataset)
- Hence, a bootstrap dataset  $x_1^*, \dots, x_n^*$  is obtained by random sampling with replacement!
- Often the bootstrap approximation of the distribution of T will improve if we somehow normalize
  T by relating it to a corresponding feature of the "true" distribution.
  - rather than approximating the distribution of  $\bar{X}_n$  by the one of  $\bar{X}_n^*$
  - better to approximate  $\bar{X}_n \mu$  by  $\bar{X}_n^* \mu^*$ , where  $\mu^* = E[\hat{F}] = \bar{x}_n = (x_1 + \ldots + x_n)/n$  [See remarks 18.1 and 18.2 of textbook]

EMPIRICAL BOOTSTRAP SIMULATION (FOR  $\bar{X}_n - \mu$ ). Given a dataset  $x_1, x_2, \ldots, x_n$ , determine its empirical distribution function  $F_n$  as an estimate of F, and compute the expectation

$$\mu^* = \bar{x}_n = \frac{x_1 + x_2 + \dots + x_n}{n}$$

corresponding to  $F_n$ .

- 1. Generate a bootstrap dataset  $x_1^*, x_2^*, \ldots, x_n^*$  from  $F_n$ .
- 2. Compute the centered sample mean for the bootstrap dataset:

$$\bar{x}_n^* - \bar{x}_n,$$

where

 $\bar{x}_n^* = \frac{x_1^* + x_2^* + \dots + x_n^*}{n}.$ 

Repeat steps 1 and 2 many times.

- Use the empirical distribution of  $\delta^* = \bar{x}_n^* \bar{x}_n$  (realizations of  $\Delta^* = \bar{X}_n^* \bar{x}_n$ )
  - for estimating  $\delta = \bar{x}_n \mu$  as  $mean(\delta^*)$
  - and then estimate  $\mu$  as  $\hat{\mu} = \bar{x}_n mean(\delta^*)$  [main idea: subtract estimated bias]
  - with estimated bias  $E[\bar{X}_n] \mu \approx E[\bar{X}_n^*] \bar{x}_n = E[\Delta^* + \bar{x}_n] \bar{x}_n \approx mean(\delta^*)$
  - with standard error  $\sqrt{Var(\bar{X}_n)} = \sqrt{Var(\bar{X}_n \mu)} \approx \sqrt{Var(\bar{X}_n^* \bar{x}_n)} = \sqrt{Var(\Delta^*)} \approx sd(\delta^*)_{/18}$

**EMPIRICAL BOOTSTRAP SIMULATION** (FOR  $\bar{X}_n - \mu$ ). Given a dataset  $x_1, x_2, \ldots, x_n$ , determine its empirical distribution function  $F_n$  as an estimate of F, and compute the expectation

$$\mu^* = \bar{x}_n = \frac{x_1 + x_2 + \dots + x_n}{n}$$

corresponding to  $F_n$ .

- 1. Generate a bootstrap dataset  $x_1^*, x_2^*, \dots, x_n^*$  from  $F_n$ .
- $2. \;$  Compute the centered sample mean for the bootstrap dataset:

$$\bar{x}_n^* - \bar{x}_n$$

where

$$\bar{x}_n^* = \frac{x_1^* + x_2^* + \dots + x_n^*}{n}.$$

Repeat steps 1 and 2 many times.

- Use the empirical distribution of  $\delta^* = \bar{x}_n^* \bar{x}_n$  for estimating
  - confidence interval  $(c_l, c_u)$  for  $\delta = \bar{x}_n \mu$  as  $(q_{\alpha/2}, q_{1-\alpha/2})$  of  $\delta^*$  distribution
  - $c_l \le \delta = \bar{x}_n \mu \le c_u$  implies  $\bar{x}_n c_u \le \mu \le \bar{x}_n c_l$ , i.e. c.i. for  $\mu$  is  $(\bar{x}_n c_u, \bar{x}_n c_l)$

boot.ci method in R confidence intervals:

- type='basic':  $(\bar{x}_n-q_{1-lpha/2},\bar{x}_n-q_{lpha/2})$  with quantiles over the distribution of  $\delta^*$
- type='perc':  $(q_{lpha/2},q_{1-lpha/2})$  with quantiles over the distribution of  $ar{x}_n^*$
- type='norm':  $(\bar{x}_n q_{1-\alpha/2}, \bar{x}_n q_{\alpha/2})$  with quantiles over  $N(mean(\delta^*), var(\delta^*))$
- type='bca': bias (and skewness) correction and acceleration

boot.ci method in R confidence intervals:

• type='stud':  $(\bar{x}_n-q_{1-\alpha/2}\frac{s_n}{\sqrt{n}},\bar{x}_n-q_{\alpha/2}\frac{s_n}{\sqrt{n}})$  with quantiles over the distribution of  $t^*$ 

EMPIRICAL BOOTSTRAP SIMULATION FOR THE STUDENTIZED MEAN. Given a dataset  $x_1, x_2, \ldots, x_n$ , determine its empirical distribution function  $F_n$  as an estimate of F. The expectation corresponding to  $F_n$  is  $\mu^* = \bar{x}_n$ .

- 1. Generate a bootstrap dataset  $x_1^*, x_2^*, \ldots, x_n^*$  from  $F_n$ .
- $2. \;\;$  Compute the studentized mean for the bootstrap dataset:

$$t^* = \frac{\bar{x}_n^* - \bar{x}_n}{s_n^* / \sqrt{n}},$$

where  $\bar{x}_n^*$  and  $s_n^*$  are the sample mean and sample standard deviation of  $x_1^*, x_2^*, \dots, x_n^*$ .

Repeat steps 1 and 2 many times.

- Bootstrap approach applies to any estimator, not only the mean
- Example 1: the German Tank problem

$$T_2 = \frac{n+1}{n}M_n - 1 \qquad \qquad E[T_2] = N$$

- Example 2: linear regression coefficients
  - ▶ 95% confidence intervals (assuming  $\underline{U_i \sim \mathcal{N}(0, \sigma^2)}$ ):

$$\hat{\beta} \pm t_{n-2,0.025} se(\hat{\beta})$$
  $\hat{\alpha} \pm t_{n-2,0.025} se(\hat{\alpha})$ 

## An application of empirical bootstrap

- Bootstrap principle: for  $X \sim F$ 
  - lacktriangle the empirical distribution of  $\Delta^*=ar{X}_n^*-ar{x}_n$  approximates the distribution of  $\Delta=ar{X}_n-\mu$
- Application: estimate  $P_F(|\bar{X}_n \mu| > 1)$  as
  - $lacksquare P_{\hat{\mathcal{F}}}(|ar{X}_n^*-ar{x}_n|>1)$  and then by the fraction of  $\delta^*=ar{x}_n^*-ar{x}_n$  such that  $|\delta^*|>1$
- How many bootstrap samples?
  - ▶ There are  $\binom{2n-1}{n-1}$  distinct bootstrap samples
  - Suggested to use at least 1000 bootstrap samples
  - ▶ **Jackknife resampling**: bootstrap samples  $x_1, \ldots, x_{i-1}, x_{i+1}, \ldots, x_n$ , for  $i = 1, \ldots, n$
- How good is the approximation by bootstrap?
  - ightharpoonup Small perturbation to data-generating process should produce small perturbation of the parameter to estimate  $(\theta)$
  - ▶ Problems with extreme values, e.g., percentiles, maximum, etc.

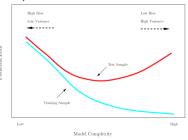

#### Risk (or Expected Prediction Error EPE)

The risk w.r.t. a loss function  $\ell_{\theta}$  is  $R(\theta_{TRUE}, \theta) = E_{(W,C) \sim f_{\theta_{TRUE}}}[\ell_{\theta}(C, W)].$ 

- Decision rule  $y_{\theta}^+(w)$  (classifier) or score function  $s_{\theta}(w)$  (binary probabilistic classifier)
- E.g., 0-1 loss  $\ell_{\theta}(c, w) = \mathbb{1}_{y_{\theta}^{+}(w) \neq c}$
- Empirical risk estimate risk on a **holdout set** (test set) of  $n_h$  observations:

$$\hat{r} = \frac{1}{n_h} \sum_{i=1}^{n_h} \ell_{\theta}(c_i, w_i)$$
 se  $= \sqrt{\frac{\hat{r}(1-\hat{r})}{n_h}}$ 

Drawbacks: variability of training/test set, and then of empirical risk estimates

#### Risk (or Expected Prediction Error EPE)

The risk w.r.t. a loss function  $\ell_{\theta}$  is  $R(\theta_{TRUE}, \theta) = E_{(W,C) \sim f_{\theta_{TRUE}}}[\ell_{\theta}(C, W)].$ 

- Decision rule  $y_{\theta}^+(w)$  (classifier) or score function  $s_{\theta}(w)$  (binary probabilistic classifier)
- E.g., 0-1 loss  $\ell_{\theta}(c, w) = \mathbb{1}_{y_{\theta}^+(w) \neq c}$
- Empirical risk estimate risk using **random sampling** (k times random split training-test):  $\hat{r} = \frac{1}{\nu} \sum_{i=1}^{k} \hat{r}^{j}$  with  $\hat{r}^{j} = \frac{1}{n} \sum_{i=1}^{n_{j}} \ell_{\theta}(c_{i}^{j}, w_{i}^{j})$
- ullet Standard deviation calculated over the k folds, with

$$se = \sqrt{\frac{1}{k-1} \sum_{j=1}^{k} (\hat{r}^{j} - \hat{r})^{2}}$$

Wrong!! As test sets (and then  $\hat{r}^{j}$ 's) are not independent!

#### Risk (or Expected Prediction Error EPE)

The risk w.r.t. a loss function  $\ell_{\theta}$  is  $R(\theta_{TRUE}, \theta) = E_{(W,C) \sim f_{\theta_{TRUE}}}[\ell_{\theta}(C, W)].$ 

- Decision rule  $y_{\theta}^+(w)$  (classifier) or score function  $s_{\theta}(w)$  (binary probabilistic classifier)
- E.g., 0-1 loss  $\ell_{\theta}(c, w) = \mathbb{1}_{y_{\theta}^{+}(w) \neq c}$
- Empirical risk estimate risk using k-fold cross-validation (independent test sets):

$$\hat{r} = \frac{1}{k} \sum_{j=1}^{k} \hat{r}^j$$
 with  $\hat{r}^j = \frac{1}{n/k} \sum_{i=1}^{n/k} \ell_{\theta}(c_i^j, w_i^j)$ 

Standard deviation calculated over the k folds, with

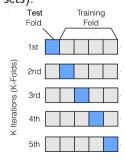

$$se = \sqrt{rac{1}{k-1}\sum_j(\hat{r}^j - \hat{r})^2}$$

**Wrong!!** As training sets (and then  $\hat{r}^{j}$ 's) are not independent! or, with

$$se = \sqrt{\frac{\hat{r}(1-\hat{r})}{n}}$$

if classifier is stable over the folds (see [Kohavi, 1995])

• Setting k = n is the **leave-one out cross-validation** (LOOCV)

- Can the bootstrap estimate prediction error?
- E.g., training = bootstrap  $x_1^*, \dots, x_n^*$ , test = original dataset  $x_1, \dots, x_n$ ?
  - ▶ No, as training-test would overlap with probability 63.2%
  - and then, prediction error would be under-estimated
- training = bootstrap  $x_1^*,\ldots,x_n^*$ , test = original dataset \ bootstrap  $\{x_1,\ldots,x_n\}\setminus\{x_1^*,\ldots,x_n^*\}$ 
  - ▶ .632 bootstrap algorithm for *k* bootstrap runs

$$\hat{r} = \frac{1}{k} \sum_{i} (0.632 \cdot \hat{r}^{j} + 0.368 \cdot \hat{r}_{tr})$$

where  $\hat{r}^{j}$  is the loss on  $j^{th}$  bootstrap run, and  $\hat{r}_{tr}$  is the loss on the original dataset

- [Kohavi, 1995, Kim, 2009] conclusions and recommendations:
  - ▶ Bootstrap has low variance, but it is extremely biased

 $\Box$  by averaging multiple k-fold cross-validation

- ▶ *k*-fold cross-validation has low bias and variance can be controlled
- ▶ Recommendation: use **repeated (stratified)** k-**fold cross-validation**, with  $k \approx 10$
- [Vanwinckelen, 2012] warns against repeated, and it recommends k-fold cross-validation

[Prove it!]

# Parametric bootstrap principle

- Let  $X_1, \ldots, X_n \sim F(\gamma)$  be a random sample
  - lacktriangle with known family  $\emph{F}$  but  $\emph{unknown}$  parameter  $\gamma$
- Estimator  $T = h(X_1, \dots, X_n)$ , e.g.,  $\bar{X}_n = (X_1 + \dots + X_n)/n$
- From a dataset  $x_1, \ldots, x_n$ , we can
  - derive a point estimate  $\hat{\theta} = h(x_1, \dots, x_n)$
  - lacktriangle or, derive an estimate  $\hat{\gamma}$  of  $\gamma$
- From  $F(\hat{\gamma})$  we can generate (a lot of) bootstrap samples  $x_1^*,\dots,x_n^*$ 
  - ▶ as realizations of  $X_1^*, \ldots, X_n^* \sim F(\hat{\gamma})$  [a form of Monte Carlo simulation] and then (a lot of) bootstrap point estimates  $\hat{\theta}^* = h(x_1^*, \ldots, x_n^*)$
- By the **Glivenko-Cantelli Thm**, the empirical distribution of  $\hat{\theta}^*$  will approximate the distribution of  $T^* = h(X_1^*, \dots, X_n^*)$  and then of T

#### Parametric bootstrap

PARAMETRIC BOOTSTRAP SIMULATION (FOR  $\bar{X}_n - \mu$ ). Given a dataset  $x_1, x_2, \ldots, x_n$ , compute an estimate  $\hat{\theta}$  for  $\theta$ . Determine  $F_{\hat{\theta}}$  as an estimate for  $F_{\theta}$ , and compute the expectation  $\mu^* = \mu_{\hat{\theta}}$  corresponding to  $F_{\hat{\theta}}$ .

- 1. Generate a bootstrap dataset  $x_1^*, x_2^*, \dots, x_n^*$  from  $F_{\hat{\theta}}$ .
- 2. Compute the centered sample mean for the bootstrap dataset:

$$\bar{x}_n^* - \mu_{\hat{\theta}},$$

where

$$\bar{x}_n^* = \frac{x_1^* + x_2^* + \dots + x_n^*}{n}.$$

Repeat steps 1 and 2 many times.

- Use the empirical distribution of  $\delta^* = \bar{x}_n^* \mu_{\hat{\theta}}$  for estimating
  - confidence interval  $(c_l, c_u)$  for  $\delta = \bar{x}_n \mu$  as  $(q_{\alpha/2}, q_{1-\alpha/2})$  of  $\delta^*$  distribution
  - $c_l \le \delta = \bar{x}_n \mu \le c_u$  implies  $\bar{x}_n c_u \le \mu \le \bar{x}_n c_l$ , i.e. c.i. for  $\mu$  is  $(\bar{x}_n c_u, \bar{x}_n c_l)$

# Application: distribution fitting

- Consider  $x_1, \ldots, x_n$  realizations of a random sample  $X_1, \ldots, X_n \sim F$
- Is the dataset from an  $Exp(\lambda)$  for some  $\lambda$ ? I.e., is it  $F = Exp(\lambda)$ ?
- We estimate  $\hat{\lambda} = 1/\bar{x}_n$

[MLE estimation]

We measure how close is the dataset to the distribution as:

$$t_{ks} = \sup_{a \in \mathbb{R}} |F_n(a) - F_{\hat{\lambda}}(a)|$$

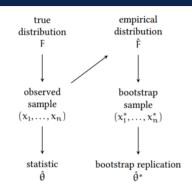

#### where:

- $ightharpoonup F_n(a)$  is the empirical cumulative distribution function of  $x_1, \ldots, x_n$
- $F_{\hat{\lambda}}(a) = 1 e^{\hat{\lambda}a}$ , for  $a \ge 0$ , is the CDF of  $Exp(\hat{\lambda})$
- $ightharpoonup t_{ks}$  is called the *Kolmogorov-Smirnov* distance
- if  $F = Exp(\lambda)$  then both  $F_n \approx F$  and  $F_{\hat{\lambda}} \approx F$ , and then  $F_n \approx F_{\hat{\lambda}}$ , so that  $t_{ks}$  is small
- if  $F \neq Exp(\lambda)$  then  $F_n \approx F \neq Exp(\lambda) \approx F_{\hat{\lambda}}$ , so that  $t_{ks}$  is large

# Application: distribution fitting

- For the software dataset from the textbook
  - $\hat{\lambda} = 0.0015$  and  $t_{ks} = 0.17$
- Is  $t_{ks} = 0.17$  expected or an extreme value?
- Let's study the distribution of the bootstrap estimator:

$$T_{ks} = \sup_{a \in \mathbb{R}} |F_n^*(a) - F_{\hat{\Lambda}^*}(a)|$$

#### where:

- $lacksquare X_1^*,\ldots,X_n^*\sim \textit{Exp}(\hat{\lambda})$  is a bootstrap sample
- $ightharpoonup F_n^*(a)$  is the empirical cumulative distribution of the bootstrap sample
- $\hat{\Lambda}^* = 1/\bar{X}_n^*$
- It turns out  $P(T_{ks} > 0.17) \approx 0$ , unlikely that  $Exp(\lambda)$  is the right model
